ABSTRACT

In general, the disclosure describes adjusting the speed of a
fan used to cool a processor in a manner that substantially
minimizes the combined power consumption of the proces-
sor and the fan. By adjusting the speed of the fan up and/or
down and then determining the combined power consump-
tion, the fan speed resulting in minimal power consumption
may be determined.

FAN CONTROL DURING LOW TEMPERATURE OPERATIONS TO REDUCE PLATFORM POWER

RELATED APPLICATIONS

The present application is related to and claims priority from U.S. patent application Ser. No. 13/431,628, filed on Mar. 27, 2012 (now U.S. Pat. No. 8,868,947 issued on Oct. 21, 2014), which claims priority from U.S. patent application Ser. No. 12/242,883, filed on Sep. 30, 2008 (now U.S. Pat. No. 8,145,926 issued on Mar. 27, 2012), both of which are incorporated herein by reference for all purposes.

BACKGROUND

Fans may be utilized in computer systems to provide cooling. The fans are used to provide cooling to the central processing unit (CPU) and other processors that generate large amounts of heat. The fans are typically turned on when the temperature of the CPU exceeds some threshold temperature. The use of the fans can reduce the temperature of the CPU and accordingly the leakage current and power consumption. In order to conserve the power consumed by the fan, the fan is typically turned off when the CPU is below some temperature or when the system is receiving power from the battery (e.g., system is unplugged) and battery conservation is desired.

BRIEF DESCRIPTION OF THE DRAWINGS

The features and advantages of the various embodiments will become apparent from the following detailed description in which:

FIG. 1 illustrates a block diagram of an example computer system with cooling provided by a fan;

FIG. 2 illustrates a graph of an example implementation of the fan based on temperature of the CPU;

FIG. 3A illustrates a graph of example power consumptions of the CPU and fan for increasing fan speeds during low temperature operations, according to one embodiment;

FIG. 3B illustrates a graph of an example overall system power consumption as the speed of the fan increases, according to one embodiment;

FIG. 3C illustrates a graph of an example overall system temperature as the speed of the fan increases, according to one embodiment;

FIG. 4 illustrates a graph of a dynamic implementation of adjusting fan speed to select an optimal speed for power conservation for low temperature (low power) operations, according to one embodiment;

FIG. 5 illustrates a graph illustrating an example static implementation of optimal fan speed over CPU temperature for low temperature (low power) operations, according to one embodiment; and

FIG. 6 illustrates an example algorithm that may be utilized to determine a target temperature and optimal fan speed based on system parameters, according to one embodiment.

DETAILED DESCRIPTION

FIG. 1 illustrates a block diagram of an example computer system **100** with cooling provided by a fan. The computer **100** receives power from a power adapter **110** that converts the AC power from a wall socket to DC power utilized by the computer **100**. The power adapter **110** pro-

vides the power to a voltage regulator (VR) **120** to generate a regulated voltage for use by a central processing unit (CPU) **130**. The power adapter **110** also provides the power to a VR **140** to generate a regulated voltage for use by a fan controller **150** and a fan **160**. A remote heat exchanger (RCE) **170** is utilized to extract heat from the CPU **130** and provide it to a location where the fan **160** provides cooling thereto. A target temperature is the temperature at which the computer **100** is desired to operate. The target temperature may vary based on the operations of the computer **100**.

As the target temperature increases, the fan will not be required to operate as much and the power consumed by the fan will be reduced. Alternatively, as the target temperature increases the CPU temperature increases and the leakage current increases resulting in the power consumed by the CPU being increased. The overall power consumed by the system **100** is based on the power consumed by the fan **160**, the CPU **130**, and other functions (not illustrated) as well as the efficiency of the VRs **120**, **140**, the fan controller **150** and other functions. The efficiencies of the VRs **120**, **140** may vary based, for example, on the operating power and temperature of the system **100**.

FIG. 2 illustrates a graph of an example implementation of the fan based on temperature of the CPU. Typically for low temperature operations, such as during CPU idle, the fan is not turned on in order to save the power required to operate the fan. Once the CPU gets into higher temperature operations associated with an operational CPU and approaches the thermal design power (TDP) of the CPU, the fan will turn on and the speed of the fan will increase with the temperature increase of the CPU.

During low temperature operations (e.g., idle) it is possible to reduce the power consumed by the CPU by cooling the CPU (reduce target temperature). The power consumed by the fan increases in order to reduce the target temperature. As the power of the CPU and the power of the fan are inversely related to one another the overall affect on the power of the system needs to be examined. In addition to reducing the temperature and power of the CPU, the operation of the fan may reduce the temperature and power of other components in the system (e.g., graphics processor). There may be a speed for which the fan may be operated that results in a maximum power savings during lower temperature operations (optimal speed for power savings).

FIG. 3A illustrates a graph of example power consumptions of the CPU **300** and fan **310** for increasing fan speeds during low temperature operations. As the fan speed increases the power consumed by the CPU **300** reduces as the temperature and leakage current are reduced. As the fan speed increases the power consumed by the fan **310** increases.

FIG. 3B illustrates a graph of an example overall system power consumption **320** as the speed of the fan increases. The overall power consumption **320** reduces as the fan is turned on and increases in speed. At this point, the power required to operate the fan is less than the power conserved by reducing the temperature of the CPU (as well as power possibly saved by reducing the temperature of other components). At a certain fan speed the overall power consumption **320** reaches a minimum (the optimal speed **330**). As the fan speed continues to increase from the optimal speed, the overall power consumption **320** begins to increase again. At this point, the power required to increase the speed of the fan is more than the power savings provided by reducing the temperature of the CPU (and other components). A first power savings **340** may be achieved by turning the fan on and increasing the fan speed to the optimal speed **330** is

3

achieved. A second power savings **350** may be achieved by reducing the fan from full speed to the optimal speed **330**.

FIG. 3C illustrates a graph of an example overall system temperature **360** as the speed of the fan increases. The overall system temperature **360** is reduced as the fan is turned on and the speed is increased. At some point, the overall temperature may level off or even increase if the power and heat required to run the fan exceeds the heat reduction in the CPU (and other components).

The control of the fan during low temperature operations may be controlled dynamically or statically. For dynamic control the system may make decisions about increasing or decreasing the fan speed based on measurements made during operation of the system. For example, the system may take measurements regarding the power consumed by the fan and CPU during operation. The system may also take measurements regarding the power consumed by other components (e.g., graphics processor). The fan, CPU and other components may require the addition of one or more sense resistors to measure power if not already provided.

Rather than measuring CPU power, the CPU may measure the temperature and use existing leakage current characteristics to determine the leakage current (and power) based thereon. The other components (e.g., graphics processor) may also calculate power consumption in a similar way. Alternatively, the system may utilize operating system (OS) estimates of platform power utilized for battery life projection to estimate the power consumption.

Regardless of how the power consumption is measured or calculated, the system may calculate the overall power of the system for a certain fan speed (e.g., measure prior to initiation of the fan). The fan speed may then be adjusted and the overall system power may be calculated again. If the overall system power was reduced the fan speed was adjusted in the correct direction while if the overall power increased the fan speed was either adjusted in the wrong direction or the previous value may be the optimal value.

FIG. 4 illustrates a graph of a dynamic implementation of adjusting fan speed to select an optimal speed for power conservation. The CPU power **400** and the fan power **410** are measured/determined for an initial fan speed (e.g., off). A determination is made as to the overall system power **420**. As illustrated, the overall system power **420** is simply based on CPU power **400** and fan power **410**. The overall system power may also take into account the power of other components (e.g., graphics processor) that may be affected by cooling.

The fan speed is then adjusted (e.g., to a faster speed) and the CPU power **400** and fan power **410** are measured/determined again and the system power **420** is determined. The measurement/determination of CPU power **400** and fan power **410** may be made after the fan has been running at the new speed for some period (e.g., time, cycles). If the change in system power **420** was negative meaning that the overall system power **420** was reduced the fan speed was adjusted correctly. For example, as the fan speed is initially increased the system power **420** will be reduced (left side of system power **420** curve). The fan will be incremented in the same direction as long as a determination is made that the system power **420** is being reduced.

When the system power **420** increases the fan speed was adjusted too much in the particular direction (e.g., for fan speed increase the fan power **410** required to operate the fan at the additional speed is more than savings in CPU power **400** at the lower temperature). The fan speed is adjusted in the opposite direction and the system power **420** is determined again. Eventually, an optimal fan speed will be

4

determined that provides the lowest system power **420** (e.g., lowest point on system power curve, point on system power curve where slope equals 0).

It is possible that the measurements result in the fan speed oscillating back and forth between two speeds. The optimal fan speed may be selected from one of those speeds or the system may allow the fan speed may oscillate back and forth. If the optimal fan speed is selected the fan may continue to operate at that speed. The system may at times adjust the fan speed from the selected optimal speed to determine if the fan speed is still optimal. The adjustment to the optimal fan speed may be done at defined periods (e.g., time, cycles) or may be based on some system parameters (e.g., change in system status, change in system temperature).

The adjustments to the fan speed may be same for each adjustment period or may vary based on conditions. For example, the fan speed may be implemented in certain increments while the system power is decreasing, and then the increments may be reduced each time a determination is made that the system power increased.

FIG. 5 illustrates a graph illustrating an example static implementation of optimal fan speed **500** over CPU temperature for low temperature (low power) operations. The optimal fan speed **500** may be calculated by an engineer at the time the computer is designed or may be calculated by an algorithm used to calculate optimal fan speed based on system parameters. The optimal fan speed may be a parameter defined in the fan controller, and the fan may operate at the defined speed based on the temperature of the CPU.

As the optimal fan speed **500** is determined during the design of the system the optimal fan speed may not equate to what would be optimal in operation due to, for example, manufacturing or operational differences. For example, if the dynamic method of defining the optimal fan speed was utilized it may determine an optimal fan speed **510** that is above the static optimal fan speed **500**. Accordingly, the system power savings may not be as much as it could have been if the fan speed was increased (e.g., on left side of FIG. 4). If the dynamic method determined that an optimal fan speed **520** below the static optimal fan speed **500**. In this case, the system power savings may not be as much as it could have been had the fan speed been reduced (e.g., on right side of FIG. 4). Whether the static optimal fan speed **500** is optimal in operation or not, use of the static optimal fan speed **500** provides system power savings that would not be available if the fan was not run during low temperature (low power) operations.

FIG. 5 includes some typical low power benchmarks (idle mode, mobile mark 2007 (MM07), and Energy Star) overlaid over the CPU temperature (the placement is relative as the CPU temperature for these benchmarks may vary based on different parameters. MM07 is a benchmark for limited CPU operations associated with conserving battery life in a portable computer and Energy Star is a benchmark for reducing energy. Utilizing the fan during these low power operations may reduce power consumed and conserve energy, and accordingly assist the systems meet these benchmarks.

FIG. 6 illustrates an example algorithm that may be utilized to determine a target temperature and optimal fan speed based on system parameters. The algorithm may be utilized for any system where the parameters are known and may not require excessive experimentation by the engineer.

Although the disclosure has been illustrated by reference to specific embodiments, it will be apparent that the disclosure is not limited thereto as various changes and modifi-

5

cations may be made thereto without departing from the scope. Reference to “one embodiment” or “an embodiment” means that a particular feature, structure or characteristic described therein is included in at least one embodiment. Thus, the appearances of the phrase “in one embodiment” or “in an embodiment” appearing in various places throughout the specification are not necessarily all referring to the same embodiment.

The various embodiments are intended to be protected broadly within the spirit and scope of the appended claims.

What is claimed:

1. A method comprising:

- 1) determining a power consumption of a computer system, wherein the power consumption of the computer system comprises at least a sum of power consumption for a cooling fan and power consumption for a device being cooled by the fan;
- 2) changing a fan speed of the fan in a first direction and determining if the power consumption of the computer system increased or decreased after said changing in the first direction;
- 3) i) if the power consumption decreased in operation 2), changing the fan speed again in the first direction;
ii) if the power consumption increased in operation 2), changing the fan speed in a second direction;
iii) if the power consumption did not change in operation 2), not changing the fan speed;
- 4) repeating operations 2) and 3);

Wherein said first direction is either increasing or decreasing the fan speed, said second direction is decreasing the fan speed if the first direction is increasing the fan speed, and the second direction is increasing the fan speed if the first direction is decreasing the fan speed.

2. The method of claim 1, wherein said determining if the power consumption of the computer system increased or decreased comprises determining if the power consumption changed by more than a predetermined amount.

3. The method of claim 1, wherein the first direction is increasing the fan speed and the second direction is decreasing the fan speed.

6

4. The method of claim 1, wherein the first direction is decreasing the fan speed and the second direction is increasing the fan speed.

5. The method of claim 1, wherein said changing the fan speed occurs at predetermined time intervals.

6. An apparatus comprising:

a fan;

a CPU;

a fan controller to control the operation of the fan, wherein the apparatus is to control a speed of the fan by:

A) determining a power consumption of a computer system, wherein the power consumption of the computer system comprises at least a sum of power consumption of the fan and power consumption of a device being cooled by the fan;

B) changing a fan speed of the fan in a first direction and determining if the power consumption of the computer system increased or decreased after said changing in the first direction;

C) i) if the power consumption decreased in operation 2), changing the fan speed again in the first direction;
ii) if the power consumption increased in operation 2), changing the fan speed in a second direction;

D) repeating operations B) and C);

wherein said first direction is either increasing or decreasing the fan speed, said second direction is decreasing the fan speed if the first direction is increasing the fan speed, and the second direction is increasing the fan speed if the first direction is decreasing the fan speed.

7. The apparatus of claim 6, wherein said determining if the power consumption of the computer system increased or decreased comprises determining if the power consumption changed by more than a predetermined amount.

8. The apparatus of claim 6, wherein the first direction is increasing the fan speed and the second direction is decreasing the fan speed.

9. The apparatus of claim 6, wherein the first direction is decreasing the fan speed and the second direction is increasing the fan speed.

10. The apparatus of claim 6, wherein said changing the fan speed is to occur at predetermined time intervals.
